

IEA Task 57

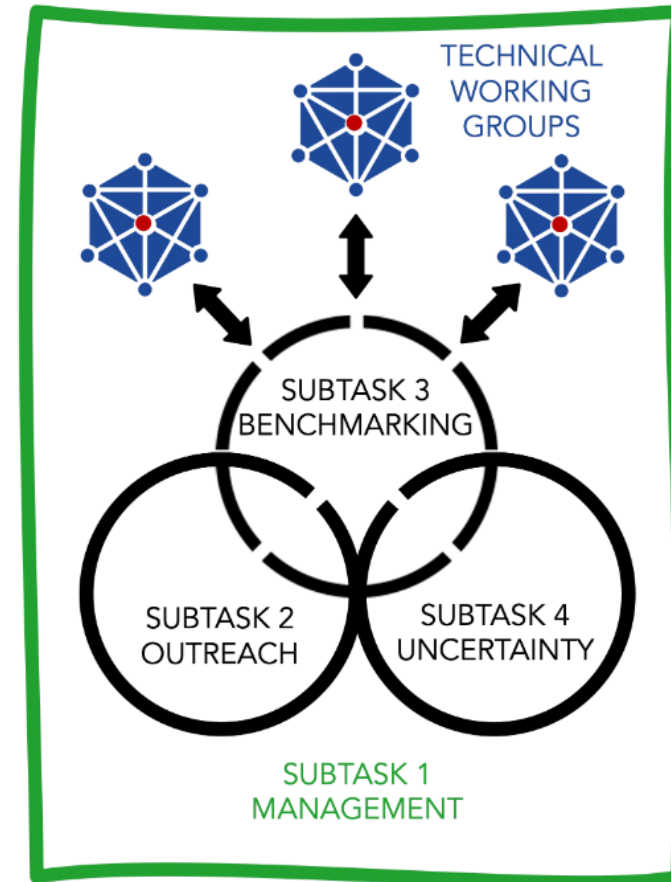

Joint Assessment of Wind Models (JAM)

JAM overview

- **Joint international collaboration:** bringing together experimentalists, computational modelers, and industry experts working with wind energy
- **Aim:** Align and integrate parallel efforts in assessing the accuracy and reliability of models used in wind energy systems, from turbine inflow to full wind farm operations
- **Duration:** February 2024 – January 2027
- **Participating countries:** 
- [Task 57 – JAM | IEA Wind TCP](#)

Objectives

- **Increase and accelerate research** yield through coordination and collaboration of validation projects
- **Produce, disseminate, and execute benchmarks** that are long-lived democratic, and standardized
- **Maximize benchmark value** with stakeholder input before and after execution
- **Reduce uncertainty in model assessment** through emphasis on inflow and uncertainty quantification
- **Recommend best practices** on model use across application spaces

Adopted from [JAM VIRTUAL KICKOFF](#)

Benchmarking

JAM builds upon IEA Task 31 WakeBench (2011-2021) primarily by extending the scope and ambition of the benchmark cases:

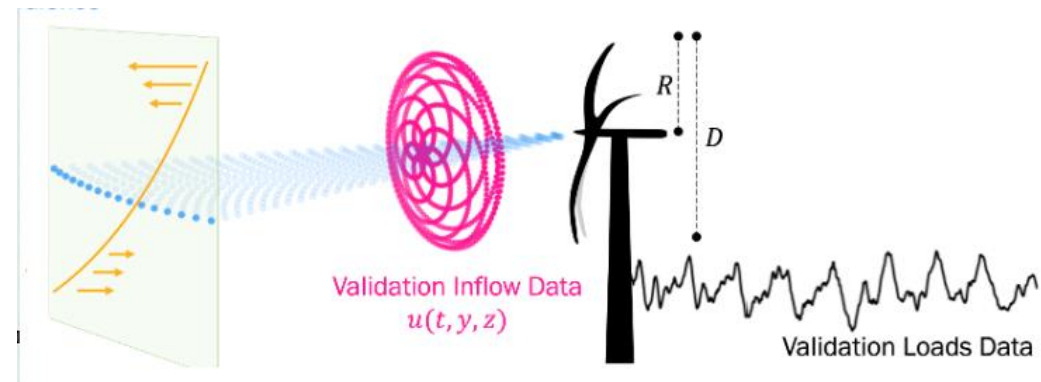

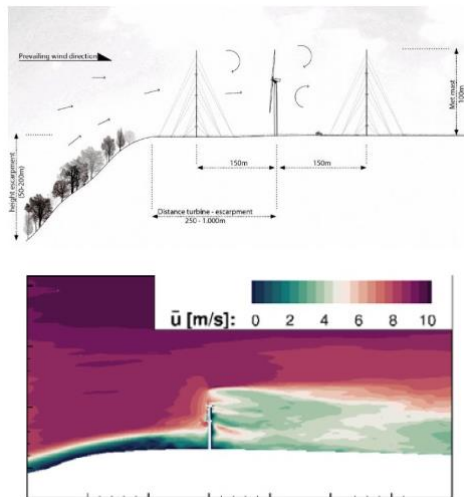

- **More comprehensive experimental data:** concurrent inflow, wake and performance data at full scale
- **Few high-quality benchmarks:** many participants, iterative execution
- **Benchmark standardization:** universal blueprint, stakeholder-driven metrics
- **Focus on inflow:** Lesson learned from previous work
- **Model assessment deep dives:** workshops with modelers to pin-point model issues

Benchmarks

- Spring 2024 - [AWAKEN](#) (diurnal cycle, two land-based wind plants)
- Fall 2024 - [RAAW](#) (turbulent inflow generation, land-based, flat terrain)
- Spring 2025 – [WINSENT](#) (complex terrain, two turbines)
- Spring 2026 - [WiValdi](#) (near shore, two turbines)

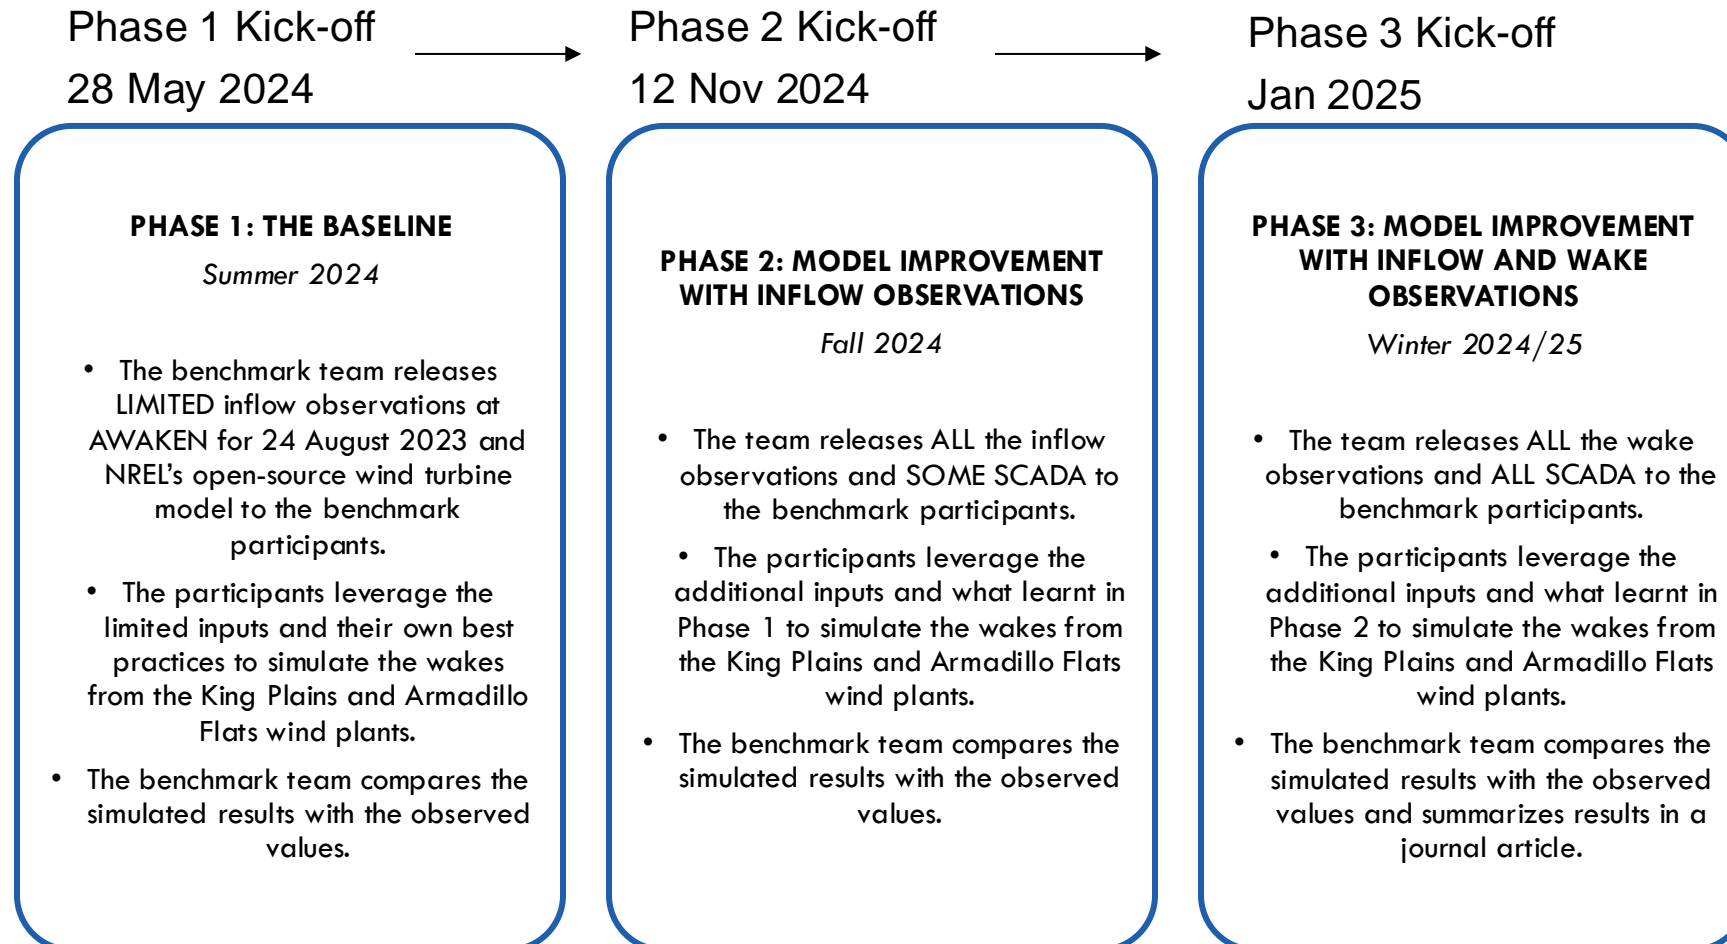

AWAKEN: The American WAKE Experiment

Multi-institutional field-campaign on wind farm–atmosphere interactions:

- Northern Oklahoma, U.S.
- 2022-2024
- 13 ground sites with numerous instruments (met masts, lidars, sonics, radars ..)
- 5 instrumented wind turbines (yellow circles)
- Multiple wind farms
- Leverage existing observational facilities (Southern Great Plains) operated by ARM

AWAKEN: A benchmark in 3 phases

AWAKEN: Selected results from phase 1

Simulation of results for August 24 2023

Power bias: $\frac{P_{simulated} - P_{observed}}{P_{observed}}$

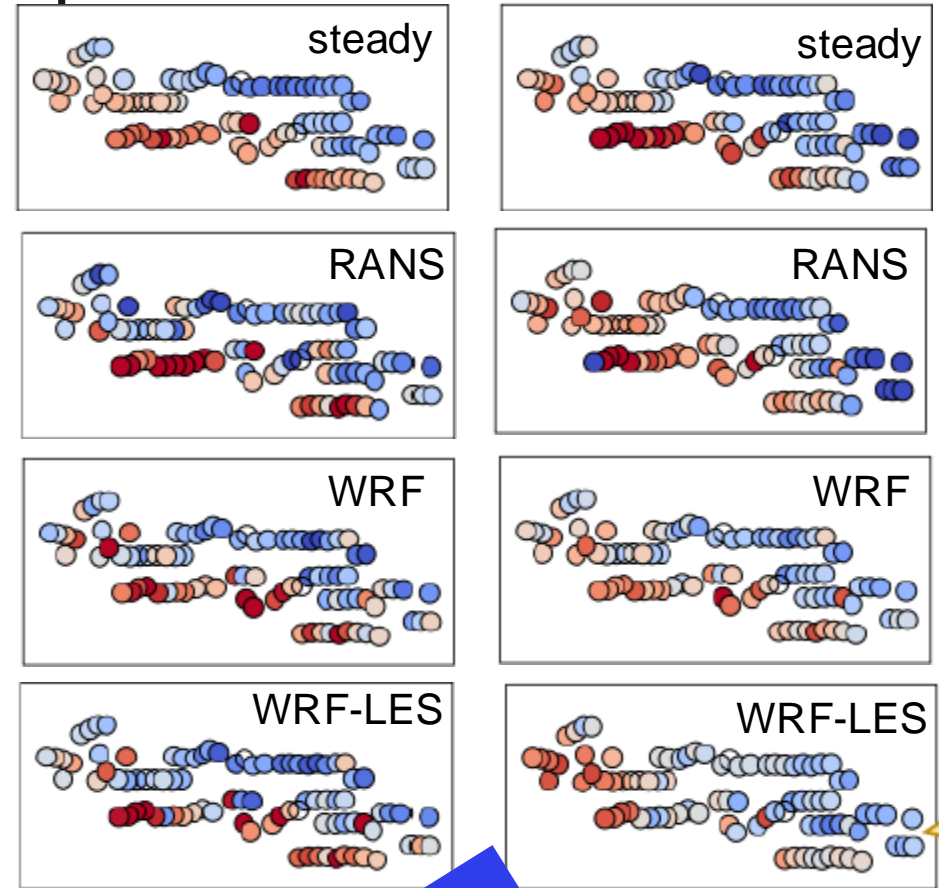

Bias in predicted power of King Plains

AWAKEN: Selected results from phase 1

Simulation results for August 24 2023

Power bias: $\frac{P_{simulated} - P_{observed}}{P_{observed}}$

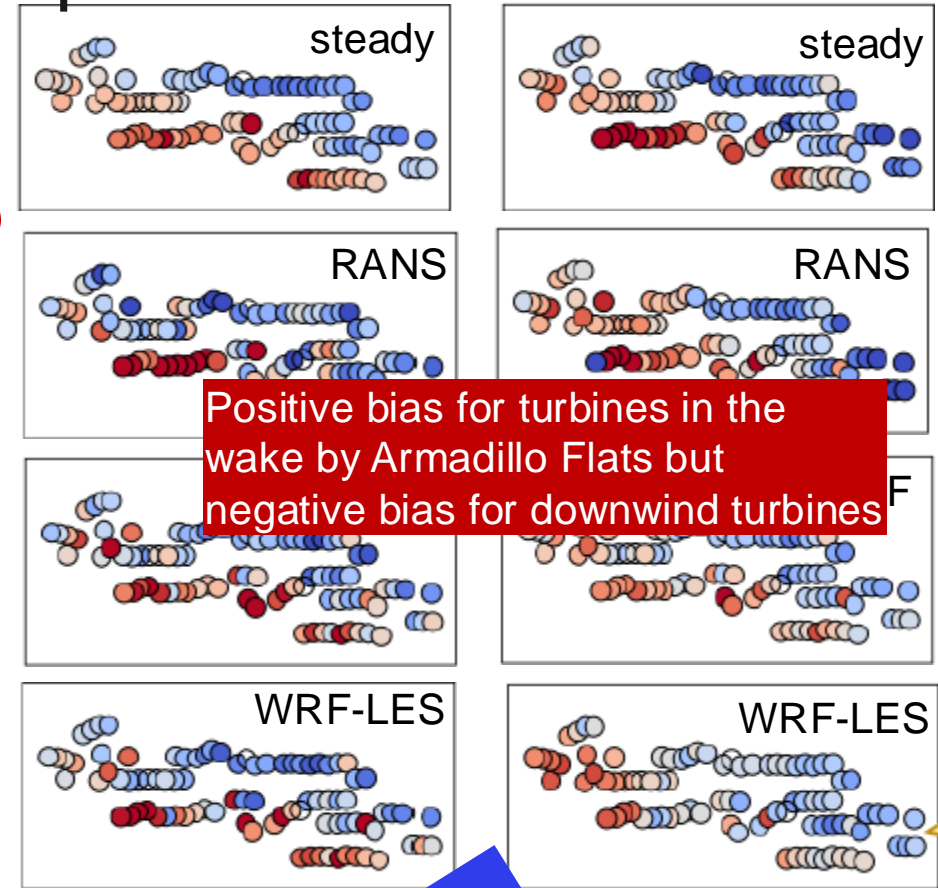

Bias in predicted power of King Plains

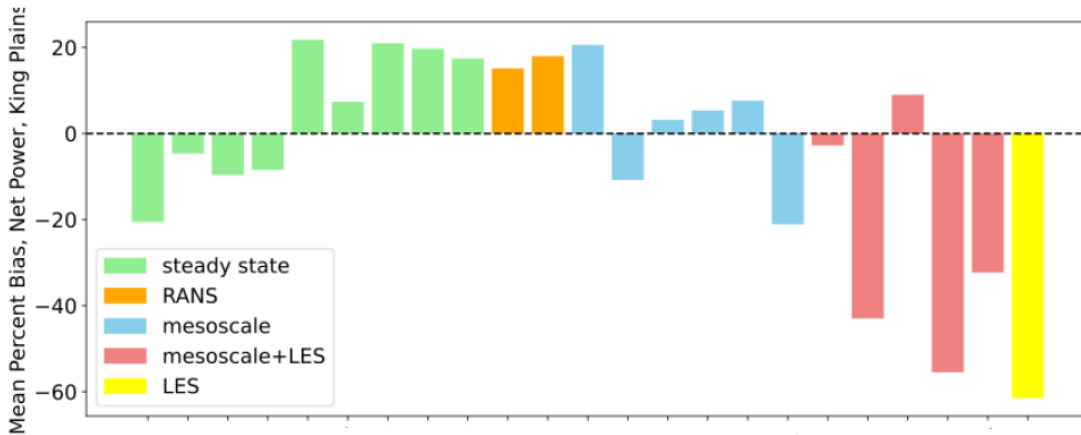

AWAKEN: Selected results from phase 1

Simulation results for August 24 2023

Power bias: $\frac{P_{simulated} - P_{observed}}{P_{observed}}$

Positive bias for turbines in the wake by Armadillo Flats but negative bias for downwind turbines

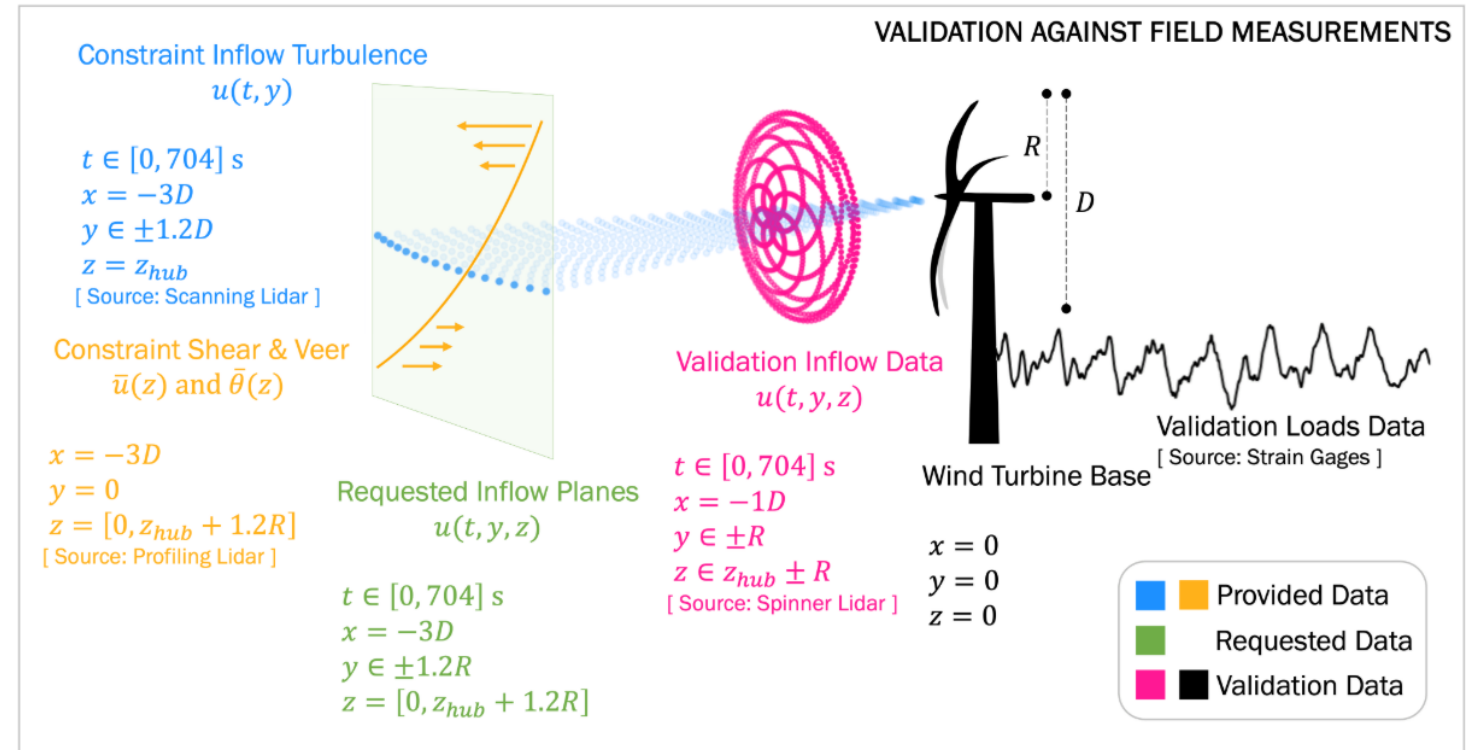

Bias in predicted power of King Plains

RAAW: Rotor inflow

- Validate methods for simulating turbulent inflows to aeroelastic wind turbine simulations.
- Quantify the effect of inflow accuracy on simulated structural loads
- Models extrapolate above and below the constraint.
- Duration: October 2024-April 2025
- [Rotor Inflow Benchmarks — rotor inflow benchmark documentation](#)
